

WEEK 2 – CURRENT STATE ASSESSMENT AND REQUIREMENTS GATHERING

End-to-End Salesforce CRM Transformation for Customer Operations and Service Management

2.1 Process Mapping

2.1.1 Current-State (AS-IS) Customer Service Workflow

The existing customer service process at GreenGrid Utilities is largely manual, fragmented, and inefficient. Service requests currently move through several disconnected stages before reaching resolution.

Step 1 – Incident Reporting

When customers experience service interruptions, such as power outages or utility-related issues, they contact the customer support center by telephone to report the problem.

Step 2 – Customer Information Retrieval

After receiving the call, support representatives manually search large Excel files to locate customer details, account information, and service location records. This stage introduces the first major bottleneck (B1) because locating information can be time-consuming.

Step 3 – Technician Assignment

Once the customer information is identified, the support representative communicates the service request to field technicians using external communication tools such as phone calls or WhatsApp messages. This manual transfer of information creates the second bottleneck (B2).

Step 4 – Field Service Execution

Assigned technicians travel to the customer location, perform the required maintenance or repairs, and document their findings using paper-based records.

Step 5 – Case Completion and Update

After the work is completed, technicians provide status updates verbally or through text messages. Customer support staff later update the Excel records manually, resulting in the third bottleneck (B3).

2.1.2 Process Challenges (Bottleneck Assessment)

a. B1 – Inefficient Customer Data Retrieval

Searching through legacy spreadsheet systems requires approximately three to five minutes per customer inquiry. This delay contributes to longer waiting times, increased call abandonment, and lower customer satisfaction.

b. B2 – Communication and Documentation Inefficiencies

Reliance on messaging applications and paper-based documentation creates inconsistencies in information sharing. The absence of a centralized system leads to fragmented records and contributes to an estimated 15% error rate when communicating job details to field personnel.

c. B3 – Delayed Data Updates

Service records are often updated several hours after field work has been completed. This delay limits management's ability to monitor operational performance and service status in real time.

2.2 Stakeholder Interviews

To better understand operational challenges and user expectations, simulated stakeholder interviews were conducted across key departments.

Customer Support Team Feedback

Support agents indicated that managing customer requests through multiple spreadsheets is inefficient and frustrating. They expressed a need for a centralized interface that would allow them to access information and manage cases within a single workspace.

Field Operations Team Feedback

Field technicians reported that limited access to customer histories and technical asset information often slows down service activities. They estimated that direct access to relevant information could reduce unnecessary repeat visits by approximately 20%.

Executive Management Feedback

Senior leadership emphasized the importance of automated reporting capabilities. Currently, management spends several hours each week manually consolidating data from multiple sources, reducing productivity and delaying decision-making.

2.3 System Requirements Documentation

2.3.1 Business Requirements (BR)

The following business requirements define the strategic objectives that the Salesforce CRM solution must support.

ID	Business Requirement	Target Outcome
BR1	Improve customer service efficiency and reduce call handling delays.	Achieve a 25% reduction in Average Handling Time (AHT).
BR2	Create standardized data management practices to eliminate fragmented information.	Maintain a centralized database with 99% data accuracy.
BR3	Improve maintenance response effectiveness for field service teams.	Increase first-time issue resolution rates by 15%.

2.3.2 Functional Requirements (FR)

These requirements describe the system features and capabilities necessary to support business operations.

ID	Functional Requirement	Priority
FR1	The system must allow users to locate complete customer records using an indexed Meter ID field within two seconds, without relying on external integrations.	High
FR2	The platform must provide a unified Service Console interface that enables support agents to record cases efficiently while handling customer calls.	High
FR3	Field technicians must be able to view assigned records and update work statuses through a secure mobile-accessible interface.	Medium
FR4	The system must automatically generate alerts for high-priority cases that remain unassigned for longer than fifteen minutes.	Medium

2.3.3 Non-Functional Requirements (NFR)

Non-functional requirements define the expected quality, security, and performance standards of the solution.

ID	Non-Functional Requirement	Technical Target
NFR1	The platform must provide reliable availability to support uninterrupted business and field operations.	Maintain at least 99.9% uptime during business hours.
NFR2	Customer information must be protected through appropriate access controls and security mechanisms.	Implement Role-Based Access Control (RBAC) across user profiles.
NFR3	The user interface should support efficient workflows and rapid information access.	Reports and dashboards should load within five seconds.

2.4 User Stories

2.4.1 User Story 1 – Customer Support Call Management

Background

During periods of high service demand, existing spreadsheet-based processes become difficult to manage and slow down customer support operations. Agents require a centralized workspace to quickly access customer information and create service cases.

User Story

As a Customer Support Agent,

I want to search for customer information using a Meter ID and create service cases from a single Service Console interface,

So that

I can handle customer requests more efficiently and minimize waiting times.

Acceptance Criteria

- Customer records must be retrievable using Meter ID within two seconds.
- Contact information and location details should automatically populate from the related account record.

2.4.2 User Story 2 – Mobile Field Service Updates

Background

Manual dispatch processes and paper-based reporting frequently result in communication errors and lost documentation. Field technicians require mobile access to assignments and service information in real time.

User Story

As a Field Technician,

I want to receive work assignments instantly and submit completion details directly from my mobile device,

So that

I can perform service activities more accurately and eliminate dependence on paper records.

Acceptance Criteria

- Technicians must receive immediate notifications when new assignments are created.
- The Technical Resolution Notes field must be completed before a work order can be marked as "Resolved."

Conclusion

Milestone 2 provides a detailed assessment of GreenGrid Utilities' current operational environment and translates stakeholder feedback into structured business and system requirements. By documenting existing workflows, identifying operational bottlenecks, and defining clear requirements, this milestone establishes a strong foundation for future-state process design, Salesforce solution architecture, and implementation planning in subsequent phases.
